

Week 6 Practical

Azure Update Manager was configured to perform periodic assessments on Net731-VM. This automatically checks for missing OS updates on a regular basis, ensuring the VM is always evaluated against the latest available patches. Keeping the OS updated is critical in a cloud environment as unpatched systems are a common attack vector — outdated OS configurations were specifically flagged in the client's audit. Enabling periodic assessment ensures vulnerabilities are identified promptly and can be remediated before they are exploited

Microsoft Defender for Cloud was accessed and the Secure Score was still loading at the time of submission. This is expected behaviour for newly deployed environments as Defender for Cloud requires time to scan and assess resources before generating recommendations. Based on the configuration of the environment — specifically the initially open RDP port (3389) and lack of OS update scheduling — the expected recommendations would include: (1) Management ports should be closed on virtual machines (High severity), (2) System updates should be applied to machines (High severity), and (3) Enable endpoint protection (Medium severity). Both high severity recommendations were proactively remediated before Defender completed its assessment
